(54) Title: PROCEDURE FOR SETTING UP A CALL IN A WIRELESS LOCAL LOOP

(57) Abstract

Procedure for setting up a call in a wireless local loop, which is based on mobile communication technology and in which terminal units (TU) are connected via a radio link to an access node (AN) and from the access node to a wired network local exchange (LE) via a standard V5 interface and in which checking functions consistent with a mobile communication specification are carried out. To accelerate call setup, checking functions are carried out during voice mode connection of the call.

WO 99/12376

PCT/FI98/00654

1

PROCEDURE FOR SETTING UP A CALL IN A WIRELESS LOCAL LOOP

The present invention relates to a procedure as defined in the preamble of claim 1.

5 In a wireless local loop (WLL, Wireless Local Loop or RLL, Radio in Local Loop), a terminal unit is connected via a wireless link to an access node (AN). The access node may consist of multiplexers, crossbar switches and various transmitting systems. The WLL
10 system may be based e.g. on technology used in mobile telephone systems, such as the GSM/DCS1800 technology (GSM, Global System for Mobile Communications; DCS, Digital Cellular System). GSM is a European digital mobile communication system standardised by ETSI. DCS-
15 1800 is a mobile communication system standardised by ETSI, which is based on the GSM specification and aims at a more effective use of microcells and which works in the frequency range of 1800 MHz. Between the terminal unit and the access node there is a base trans-
20 ceiver station, through which call signals received from the terminal unit over a radio channel are transmitted via the access node to a public telephone network and vice versa. The access node can be connected to the telephone exchange using e.g. a V5.2 protocol
25 consistent with the ETS 300 347-1 standard or a V5.1 protocol consistent with the ETS 300 324-1 standard. The access node functions as a converter between GSM signalling and V5 signalling.

During call setup in a local loop, various
30 checking functions related to network security management are carried out. The checking functions are designed to prevent illicit access to the network for users who have no right to use it, and to prevent the use of e.g. a mobile station reported stolen. The
35 checking operations defined by the GSM specifications, carried out during call setup, retard the call setup

WO 99/12376

PCT/FI98/00654

2

process so that the V5 signalling time-outs are tripped and the call must be disconnected even though it is most likely to be successful. In a wireless local loop, fast setup of an outgoing call is particularly important.

An operation retarding call setup is e.g. change of the subscriber identity code (TMSI reallocation), which means changing the temporary subscriber identity code assigned for the subscriber by the visitor location register and allowing confidential subscriber identification e.g. during the call. Another check retarding call setup is the verification of the subscriber's access right, i.e. subscriber authentication, which means checking the subscriber data of a mobile station and preventing illicit access to the network. A third check retarding call setup is the verification of the subscriber's equipment identity code (IMEI check). To check the equipment identity code, it is compared with a register of equipment identity codes of mobile stations reported stolen and/or defective. IMEI is an international mobile station equipment identity code, by means of which a mobile station can be unambiguously identified.

Especially the time-outs in the PSTN protocol in the V5 interface (standard ETS 300 324-1 1 13) cause problems in call setup in a wireless local loop system. For instance, in the case of a terminating call, the time-out according to the V5 PSTN protocol between the start message and the acknowledgement message (the telephone rings) is max. 4 seconds (standard ETS 300 324-1 13.6).

The object of the present invention is to eliminate the drawbacks described above.

A specific object of the invention is to present a procedure that can be used to accelerate call setup so that unnecessary tripping of time-outs and needless disconnection of calls are avoided and the

WO 99/12376

PCT/FI98/00654

3

time available for the signalling needed for the call setup itself is increased.

The procedure of the invention is characterised by what is presented in claim 1.

5 According to the invention, to accelerate call setup, checking functions are performed during voice mode connection of the call instead of being performed during call setup. The invention provides the advantage that more time is made available for the
10 signalling needed for call setup while possible tripping of time-outs and unnecessary disconnection of the call are avoided.

In an embodiment of the procedure, subscriber's terminal units are connected to an access
15 node via a radio link consistent with the GSM specification and checking functions are carried out, said functions comprising change of the subscriber identity code (TMSI reallocation), verification of subscriber authenticity (authentication) and/or verification of
20 the subscriber's equipment identity code (IMEI check).

In an embodiment of the procedure, the change of the subscriber identity code is TMSI reallocation consistent with the GSM 04.08 4.3.1. standard.

In an embodiment of the procedure, the verification of subscriber authenticity is an authentication
25 consistent with the GSM 04.08. 4.3.2 standard.

In an embodiment of the procedure, the verification of the subscriber's equipment identity code is an IMEI check consistent with the GSM 04.08. 4.3.2
30 standard.

In an embodiment of the procedure, the V5 interface is a V5.2 interface consistent with the ETS 300 347-1 standard.

In an embodiment of the procedure, the V5 interface is a V5.1 interface consistent with the ETS
35 300 324-1 standard.

WO 99/12376

PCT/F198/00654

4

The figure presents a signalling diagram representing a call originated by a terminal unit TU in a wireless local loop and substantially corresponding to a mobile-originated call MOC consistent with the GSM specifications. The system components in the diagram are a base transceiver station BTS, an access node AN, i.e. a node of an access network, and a local exchange LE.

The access node AN has three program segments called registers. These are an equipment identity register, an authentication register and, hierarchically above these, a visitor location register. The equipment identity register contains the international mobile station equipment identity numbers (IMEI). An equipment identity number may be placed on a white, grey or black list, and in response to an IMEI check the equipment identity register returns the list colour of the IMEI concerned. The authentication register produces the triplets needed in authentication and contains the data required for authentication. The functions of the visitor location register include making the decision about carrying out the checks.

In the GSM/DCS world, the following register terms are used: authentication centre AUC; AC, equipment identity register EIR and visitor location register VLR. In conjunction with a wireless local loop, the visitor location register is designated WVR (wireless fixed register).

Call setup in a wireless local loop in the so-called non-transparent mode as presented in the figure is substantially identical with call setup in a conventional GSM system. In a wireless local loop system, the access node AN also comprises functions that are included in the mobile switching centre/visitor location register MSC/VLR and home location register/authentication centre/equipment identity register (HLR/AC/EIR) of an ordinary GSM system. In a wireless

WO 99/12376

PCT/FI98/00654

5

local loop, the subscriber terminal units communicate with the access node AN by radio. The signalling between the terminal unit and the access node AN is message based signalling consistent with the GSM specifications (GSM/DCS). The access node AN is connected to a wired network local exchange LE via a V5.2 interface consistent with the ETS 300 347-1 standard.

When the subscriber picks up the receiver, the terminal unit generates a local dial tone. The subscriber has a predetermined period of time to dial the first digit. The dial tone goes out as soon as the first digit has been dialled. The item numbers below correspond to the numbering in the figure.

1. Call setup is started upon the lapse of a predetermined period of time after the last digit has been dialled. The terminal unit TU requests a call by sending a CHANNEL REQUEST message to the base transceiver station BTS.

2. The base transceiver station BTS transmits a CHANNEL_REQUIRED message to the access node AN, which starts a search to find a communication channel.

3. After a communication channel has been successfully allocated, the access node AN activates the channel by sending a CHANNEL ACTIVATION message to the base transceiver station BTS.

4. The base transceiver station acknowledges activation by returning a CHANNEL ACTIVATION ACK message. The base transceiver station BTS starts transmission and reception on this channel using the power and timing data received in this message.

5. After the communication channel has been successfully activated, the access node AN sends an IMMEDIATE ASSIGNMENT COMMAND message to the base transceiver station BTS.

6. This message contains an IMMEDIATE ASSIGNMENT message, which the base transceiver station BTS sends to the terminal unit TU.

WO 99/12376

PCT/F198/00654

6

7. Having received the IMMEDIATE ASSIGNMENT message, the terminal unit TU is tuned to the specified communication channel and starts setting up a signalling link over the network. The terminal unit TU
5 sends a layer-2 SABM message to the base transceiver station BTS via the communication channel. The SABM contains a layer-3 service request message.

8. The base transceiver station sends the service request of the terminal unit further to the
10 access node AN in an ESTABLISH INDICATION message, which includes the subscriber's temporary mobile subscriber identity (TMSI) code.

9. The base transceiver station BTS acknowledges the SABM message by sending a UA frame to the
15 terminal unit TU.

10. The access node finds the subscriber's L3 address (using the TMSI and IMSI) and checks the state of the corresponding V5 interface. If call setup is allowed, the access node AN sends an ESTABLISH message
20 to the local exchange LE.

11. At the same time, the access node AN starts encryption by sending an ENCRYPTION COMMAND message to the base transceiver station BTS. The base transceiver station BTS analyses the command. If en-
25 cryption is needed, the base transceiver station BTS activates a demodulator for the deciphering of the encryption.

12. If encryption is used, the base transceiver station BTS sends a CIPHERING MODE COMMAND mes-
30 sage to the terminal unit TU.

13.-14. The local exchange LE sends to the access node AN an ALLOCATION message, which contains the time slot used in the V5.2 interface. The access node AN acknowledges this by sending an ALLOCATION
35 COMPLETE message to the local exchange LE.

15. After receiving the CIPHERING MODE COMMAND message, the terminal unit TU starts encryp-

WO 99/12376

PCT/F198/00654

7

tion deciphering and ciphering using an available ciphering key and returns to the base transceiver station BTS, in ciphered form, a CIPHERING MODE COMPLETE message or the next message it is to send. Upon receiving the CIPHERING MODE COMPLETE message (or any layer-2 frame correctly ciphered), the base transceiver station BTS starts encryption and transfers the message transparently to the access node AN.

16. When the local exchange LE is ready to receive a dialled number, it sends an ESTABLISH ACK message to the access node AN. A connection between the access node AN and the local exchange LE is set up and the speech path is connected through.

17. The terminal unit TU starts call setup by a SETUP message, which contains e.g. the number of the called subscriber and the call type (voice/data). The access node AN checks in the VLR/HLR database whether call setup is allowed for the subscriber. If the right conditions are fulfilled, then the access node AN sends the DTMF (dual tone multi-frequency) numbers (together with the VS messages) to the local exchange LE.

18. Having sent the numbers, the access node sends a CALL PROCEEDING message to the terminal unit TU, indicating that the call is under processing.

19.-22. The channel mode is changed from signalling to voice via a "mode modify" procedure. First, the access node AN sends a MODE MODIFY message to the base transceiver station BTS to change the channel mode. Synchronisation by a transcoder begins. After receiving a MODE MODIFY ACK message, the access node starts the channel mode change process and sends a CHANNEL MODE MODIFY message to the terminal unit TU. This command is transparent to the base transceiver station BTS. Having received the CHANNEL MODE MODIFY message, the terminal unit TU changes the channel mode from signalling to voice and sends an acknowledgement

WO 99/12376

PCT/FI98/00654

8

to the access node AN with a CHANNEL MODE MODIFY ACK message. This message, too, is transparent to the base transceiver station BTS.

23.-24. The terminal unit TU is set to voice mode by sending a CONNECT message to it. The terminal unit TU acknowledges this by sending a CONNECT ACK message. The subscriber now hears the ring-back tone from the local exchange LE.

25.-26. If the visitor location register VLR of the access node does not recognise the temporary TMSI code, then the international mobile subscriber identity IMSI is requested by an IDENTIFICATION REQUEST message. In response, an IDENTIFICATION RESPONSE message is sent to the terminal unit TU.

27. The access node AN starts authentication by sending an AUTHENTICATION REQUEST message to the terminal unit TU.

28 The terminal unit TU sends a calculated response in an AUTHENTICATION RESPONSE message to the access node AN.

The invention is not restricted to the examples of its embodiments described above, but many variations are possible within the scope of the inventive idea defined by the claims.
